The quantum correlations of two or more entangled particles present the possibility of stronger-than-classical outcome coincidences. We review the standard cases of two and four two-state particles. We also investigate two-partite correlations of spin one and spin three-half quanta in a state satisfying a uniqueness property in the sense that knowledge of an outcome of one particle observable entails the certainty that, if this observable were measured on the other particle(s) as well, the outcome of the measurement would be a unique function of the outcome of the measurement performed.

1. Introduction

The possibility of a peculiar and “mind-boggling” type of connectedness between two or more spatially separated particles beyond classical correlations surprised the quantum pioneers in their early exploration of quanta. Already Schrödinger [1–3] noted that a state of several quantized particles or quanta could be *entangled* (in Schrödinger’s own German terminology “*verschränkt*”) in the sense that it cannot be represented as the product of states of the isolated, individual quanta, but is rather defined by the *joint* or *relative* properties of the quanta involved [4, 5]. Typical examples of such joint properties of entangled states are the propositions, “when measured along two or more different directions, two spin one-half particles have opposite spin” (defining the Bell singlet state), or “when measured along a particular direction, three spin one-half particles have identical spin” (one of the three defining properties of the Greenberger-Horne-Zeilinger-Mermin state).

With respect to the outcome of certain measurements on the individual particles in an entangled state, the observation of stronger-than-classical correlations even for nonlocal, i.e., spatially and even causally separated, quanta in “delayed choice” measurements has been experimentally verified [6]. A typical phenomenologic criterion of such correlations is the *increased* or *decreased* frequency of the occurrence of certain coincidences of outcomes, such as the more- or less-often-than-classically expected recordings of joint spin up and down measurements labelled by “++,” “+-,” “-+” or “--,” respectively.

Entanglement or multipartite connectedness is no phenomenon associated with only a small number of quanta, but could in principle extend to any macroscopic size; a typical example being the spatially extended states of Cooper pairs in phonon mediated superconductors [7] and of other many-body systems [8].

What is the physical meaning of statements referring to stronger-than-classical quantum correlations? First, as has been already mentioned, there is a direct, operational meaning: certain joint outcomes of single particle measurements, when collected and compared to each other, appear to occur more or less often than could be expected classically. Second, the resulting frequencies, as well as the quantum theoretical probabilities and correlations derived from the Born rule or Gleason’s theorem, seem to contradict the “*conditions of possible experience*” investigated by Boole [9, 10] and in later times by Bell and others [11–13]. Third, the quantum correlations indicate that quantum probabilities cannot be based upon the convex sum of classical two-valued measures, because there are no two-valued measures (interpretable as classical global truth assignments) for quantized systems with more than two mutually exclusive outcomes [14–22].

Stated pointedly, the “magic” behind the quantum correlations as compared to classical correlations resides in the fact that, for almost all measurement directions (despite collinear or orthogonal ones), an observer “Alice,” when recording some outcome of a measurement, can be sure that her partner “Bob,” although spatially and causally disconnected from her, is either more or less likely to record a particular measurement outcome on his side. However, because of the randomness [23] and uncontrollability [24] of the individual events, and because of the no-cloning

theorem [25, pp. 39-40], no classically useful information can be transferred from Alice to Bob, or *vice versa*: The parameter independence [26, 27] and outcome dependence of otherwise random events ensures that the nonlocal correlations among quanta cannot be directly used to communicate classical information. The correlations of the joint outcomes on Alice's and Bob's sides can only be verified by collecting all the different outcomes *ex post facto*, recombining joint events one-by one [28]. Nevertheless, there are hopes and visions to utilize nonlocal quantum correlations for a wide range of explanations and applications; for instance in quantum information theory [29] and life sciences [30].

In what follows a few known and novel quantum correlations will be systematically enumerated. We shall derive the correlations between two and four two-state particles in singlet states. We also derive the correlations of two three-, four- and general d -state particles in a singlet state.

Singlets are states of two or more quantum particles whose total angular momentum is zero, although the angular momenta of the constituents are not. They have the advantage that they are *form invariant* with respect to directional changes; i.e., they “look the same,” regardless of the measurement direction. Singlet states of two particles have the additional advantage that they satisfy a *uniqueness property* [31] in the sense that knowledge of an outcome of one particle observable entails the certainty that, if this observable were measured on the other particle(s) as well, the outcome of the measurement would be a unique function of the outcome of the measurement performed. A *counterfactual argument* [14, p. 243] envisioned by Einstein-Podolsky-Rosen (EPR) [32] claims to measure and infer with certainty two nonco-measurable, incompatible observables associated with noncommuting operators counterfactually. One context is measured on one side of the EPR setup, the other context on the other side of it. By the uniqueness property of certain two-particle states, knowledge of a property of one particle entails the certainty that, if this property were measured on the other particle as well, the outcome of the measurement would be a unique function of the outcome of the measurement performed. This makes possible the measurement of one observable, *as well as* the *simultaneous counterfactual inference* of another incompatible observable. Because, one could argue, that although one has actually measured on one side a different, incompatible observable compared to the observable measured on the other side, *if* on both sides the same observable *would be measured*, the outcomes on both sides *would be uniquely correlated*. Hence measurement of one observable per side is sufficient, for the outcome could be counterfactually inferred from the measurements on the other side.

2. Two particle correlations

In what follows, spin state measurements along certain directions or angles in spherical coordinates will be considered. Let us, for the sake of clarity, first specify and make precise what we mean by “direction of measurement.” Following, e.g., Ref. [33, p. 1, Fig. 1], and Fig. 1, when not specified otherwise, we consider a particle travelling along the positive z -axis; i.e., along $0Z$, which is taken to be horizontal. The x -axis along $0X$ is also taken to be horizontal. The remaining y -axis is taken vertically along $0Y$. The three axes together form a right-handed system of coordinates.

The Cartesian (x, y, z) -coordinates can be translated into spherical coordinates (r, θ, φ) via $x = r \sin \theta \cos \varphi$, $y = r \sin \theta \sin \varphi$, $z = r \cos \theta$, whereby θ is the polar angle between the axes $0Z$ and $0X$, with $0 \leq \theta \leq \pi$, and φ is the azimuthal angle between the axes $0X$ and $0Y$ with $0 \leq \varphi < 2\pi$, respectively. We shall only consider directions taken from the origin 0 , characterized by the angles θ and φ , assuming a unit radius $r = 1$.

Consider two particles or quanta. On each one of the two quanta, certain measurements (such as the spin state or polarization) of (dichotomic) observables $O(a)$ and $O(b)$ along the directions a and b , respectively, are performed. The individual outcomes are encoded or labeled by the symbols “ $-$ ” and “ $+$,” or values “ -1 ” and “ $+1$ ” are recorded along the directions a for the first particle, and b for the second particle, respectively. (Suppose that the measurement direction a at “Alice’s location” is unknown to an observer “Bob” measuring b and *vice versa*.) A two-particle correlation function $E(a, b)$ is defined by averaging over the product of the outcomes $O(a)_i, O(b)_i \in \{-1, 1\}$ in the i th experiment for a total of N experiments; i.e.,

$$E(a, b) = \frac{1}{N} \sum_{i=1}^N O(a)_i O(b)_i. \quad (1)$$

Рис. 1: Coordinate system for measurements of particles travelling along OZ

Quantum mechanically, we shall follow a standard procedure for obtaining the probabilities upon which the correlation coefficients are based. We shall start from the angular momentum operators, as for instance defined in Schiff's *"Quantum Mechanics"* [34, Chap. VI, Sec.24] in arbitrary directions, given by the spherical angular momentum co-ordinates θ and φ , as defined above. Then, the projection operators corresponding to the eigenstates associated with the different eigenvalues are derived from the dyadic (tensor) product of the normalized eigenvectors. In Hilbert space based [35] quantum logic [36], every projector corresponds to a proposition that the system is in a state corresponding to that observable. The quantum probabilities associated with these eigenstates are derived from the Born rule, assuming singlet states for the physical reasons discussed above. These probabilities contribute to the correlation coefficients.

2.1 Two-state particles

2.1.1 Classical case

For the two-outcome (e.g., spin one-half case of photon polarization) case, it is quite easy to demonstrate that the *classical* correlation coefficient in the plane perpendicular to the direction connecting the two particles is a *linear* function of the azimuthal measurement angle. Assume uniform distribution of (opposite but otherwise) identical "angular momenta" shared by the two particles and lying on the circumference of the unit circle in the plane spanned by OX and OY , as depicted in Figs. 1 and 2.

Consider the arc lengths on the unit circle $A_+(a, b)$ and $A_-(a, b)$ which, normalized by the circumference of the unit circle, correspond to the frequency of occurrence of even ("++" and "--") and odd ("+-" and "-+") parity pairs of events, respectively. Thus, $A_+(a, b)$ and $A_-(a, b)$ are proportional to the positive and negative contributions to the correlation coefficient. One obtains for $0 \leq \theta = |a - b| \leq \pi$; i.e.,

$$E_{cl,2,2}(\theta) = E_{cl,2,2}(a, b) = \frac{1}{2\pi} [A_+(a, b) - A_-(a, b)] = \frac{1}{2\pi} [2A_+(a, b) - 2\pi] = \frac{2}{\pi}|a - b| - 1 = \frac{2\theta}{\pi} - 1, \quad (2)$$

where the subscripts stand for the number of mutually exclusive measurement outcomes per particle, and for the number of particles, respectively. Note that $A_+(a, b) + A_-(a, b) = 2\pi$.

The exchange of a single bit between particles results in classical correlations of the form [37]

$$E_{cl, 1 \text{ bit exchange}, 2, 2}(\theta) = H\left(\theta - \frac{3\pi}{4}\right) - H\left(\frac{\pi}{4} - \theta\right) - 2\left(1 - \frac{2}{\pi}\theta\right) H\left(\theta - \frac{\pi}{4}\right) H\left(\frac{3\pi}{4} - \theta\right), \quad (3)$$

Рис. 2: Planar geometry demonstrating the classical two two-state particles correlation. The left circle represents the positions on the unit circle which correspond to positive or negative $O(a)$; the second circle represents the positions on the unit circle which correspond to positive or negative $O(b)$; and the right circle represents the positions on the unit circle which correspond to positive or negative $O(a)O(b)$. As only the absolute value of the difference of the two angles a and b enters, one may set $|a - b| = \theta$.

where H stands for the Heaviside (unit) step function. The bit exchange “enhances” the classical correlation $E_{cl,2,2}(\theta)$ without a bit exchange to the extent that they violate certain “conditions of possible experience;” in particular the Clauser-Horne-Shimony-Holt inequalities, maximally [38].

2.1.2 Quantum case

The two spin one-half particle case is one of the standard quantum mechanical exercises, although it is seldomly computed explicitly. For the sake of completeness and with the prospect to generalize the results to more particles of higher spin, this case will be enumerated explicitly. In what follows, we shall use the following notation: Let $|+\rangle$ denote the pure state corresponding to $\hat{\mathbf{e}}_1 = (0, 1)$, and $|-\rangle$ denote the orthogonal pure state corresponding to $\hat{\mathbf{e}}_2 = (1, 0)$. The superscript “ T ,” “ $*$ ” and “ \dagger ” stand for transposition, complex and hermitian conjugation, respectively.

In finite-dimensional Hilbert space, the matrix representation of projectors $E_{\mathbf{a}}$ from normalized vectors $\mathbf{a} = (a_1, a_2, \dots, a_n)^T$ with respect to some basis of n -dimensional Hilbert space is obtained by taking the dyadic product; i.e., by

$$E_{\mathbf{a}} = [\mathbf{a}, \mathbf{a}^\dagger] = [\mathbf{a}, (\mathbf{a}^*)^T] = \mathbf{a} \otimes \mathbf{a}^\dagger = \begin{pmatrix} a_1 \mathbf{a}^\dagger \\ a_2 \mathbf{a}^\dagger \\ \dots \\ a_n \mathbf{a}^\dagger \end{pmatrix} = \begin{pmatrix} a_1 a_1^* & a_1 a_2^* & \dots & a_1 a_n^* \\ a_2 a_1^* & a_2 a_2^* & \dots & a_2 a_n^* \\ \dots & \dots & \dots & \dots \\ a_n a_1^* & a_n a_2^* & \dots & a_n a_n^* \end{pmatrix}. \quad (4)$$

The tensor or Kronecker product of two vectors \mathbf{a} and $\mathbf{b} = (b_1, b_2, \dots, b_m)^T$ can be represented by

$$\mathbf{a} \otimes \mathbf{b} = (a_1 \mathbf{b}, a_2 \mathbf{b}, \dots, a_n \mathbf{b})^T = (a_1 b_1, a_1 b_2, \dots, a_n b_m)^T \quad (5)$$

The tensor or Kronecker product of some operators

$$A = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{pmatrix} \text{ and } B = \begin{pmatrix} b_{11} & b_{12} & \dots & b_{1m} \\ b_{21} & b_{22} & \dots & b_{2m} \\ \dots & \dots & \dots & \dots \\ b_{m1} & b_{m2} & \dots & b_{mm} \end{pmatrix} \quad (6)$$

is represented by an $nm \times nm$ -matrix

$$A \otimes B = \begin{pmatrix} a_{11}B & a_{12}B & \dots & a_{1n}B \\ a_{21}B & a_{22}B & \dots & a_{2n}B \\ \dots & \dots & \dots & \dots \\ a_{n1}B & a_{n2}B & \dots & a_{nn}B \end{pmatrix} = \begin{pmatrix} a_{11}b_{11} & a_{11}b_{12} & \dots & a_{1n}b_{1m} \\ a_{11}b_{21} & a_{11}b_{22} & \dots & a_{2n}b_{2m} \\ \dots & \dots & \dots & \dots \\ a_{nn}b_{m1} & a_{nn}b_{m2} & \dots & a_{nn}b_{mm} \end{pmatrix}. \quad (7)$$

Observables

Let us start with the spin one-half angular momentum observables of a *single* particle along an arbitrary direction in spherical co-ordinates θ and φ in units of \hbar [34]; i.e.,

$$M_x = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad M_y = \frac{1}{2} \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad M_z = \frac{1}{2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (8)$$

The angular momentum operator in arbitrary direction θ, φ is given by its spectral decomposition

$$\begin{aligned} S_{\frac{1}{2}}(\theta, \varphi) &= xM_x + yM_y + zM_z = M_x \sin \theta \cos \varphi + M_y \sin \theta \sin \varphi + M_z \cos \theta \\ &= \frac{1}{2} \sigma(\theta, \varphi) = \frac{1}{2} \begin{pmatrix} \cos \theta & e^{-i\varphi} \sin \theta \\ e^{i\varphi} \sin \theta & -\cos \theta \end{pmatrix} \\ &= -\frac{1}{2} \begin{pmatrix} \sin^2 \frac{\theta}{2} & -\frac{1}{2} e^{-i\varphi} \sin \theta \\ -\frac{1}{2} e^{i\varphi} \sin \theta & \cos^2 \frac{\theta}{2} \end{pmatrix} + \frac{1}{2} \begin{pmatrix} \cos^2 \frac{\theta}{2} & \frac{1}{2} e^{-i\varphi} \sin \theta \\ \frac{1}{2} e^{i\varphi} \sin \theta & \sin^2 \frac{\theta}{2} \end{pmatrix} \\ &= -\frac{1}{2} \left\{ \frac{1}{2} [\mathbb{I}_2 - \sigma(\theta, \varphi)] \right\} + \frac{1}{2} \left\{ \frac{1}{2} [\mathbb{I}_2 + \sigma(\theta, \varphi)] \right\}. \end{aligned} \quad (9)$$

The orthonormal eigenstates (eigenvectors) associated with the eigenvalues $-\frac{1}{2}$ and $+\frac{1}{2}$ of $S_{\frac{1}{2}}(\theta, \varphi)$ in Eq. (9) are

$$\begin{aligned} |-\rangle_{\theta, \varphi} \equiv \mathbf{x}_{-\frac{1}{2}}(\theta, \varphi) &= e^{i\delta_+} \begin{pmatrix} -e^{-\frac{i\varphi}{2}} \sin \frac{\theta}{2}, e^{\frac{i\varphi}{2}} \cos \frac{\theta}{2} \end{pmatrix}, \\ |+\rangle_{\theta, \varphi} \equiv \mathbf{x}_{+\frac{1}{2}}(\theta, \varphi) &= e^{i\delta_-} \begin{pmatrix} e^{-\frac{i\varphi}{2}} \cos \frac{\theta}{2}, e^{\frac{i\varphi}{2}} \sin \frac{\theta}{2} \end{pmatrix}, \end{aligned} \quad (10)$$

respectively. δ_+ and δ_- are arbitrary phases. These orthogonal unit vectors correspond to the two orthogonal projectors

$$F_{\mp}(\theta, \varphi) = \frac{1}{2} [\mathbb{I}_2 \mp \sigma(\theta, \varphi)] \quad (11)$$

for the spin down and up states along θ and φ , respectively. By setting all the phases and angles to zero, one obtains the original orthonormalized basis $\{|-\rangle, |+\rangle\}$.

In what follows, we shall consider two-partite correlation operators based on the spin observables discussed above.

(i) Two-partite angular momentum observable

If we are only interested in spin state measurements with the associated outcomes of spin states in units of \hbar , Eq. (13) can be rewritten to include all possible cases at once; i.e.,

$$S_{\frac{1}{2}\frac{1}{2}}(\hat{\theta}, \hat{\varphi}) = S_{\frac{1}{2}}(\theta_1, \varphi_1) \otimes S_{\frac{1}{2}}(\theta_2, \varphi_2). \quad (12)$$

(ii) General two-partite correlation observables

The two-particle projectors $F_{\pm\pm}$ or, by another notation, $F_{\pm_1\pm_2}$ to indicate the outcome on the first or the second particle, corresponding to a two spin- $\frac{1}{2}$ particle joint measurement aligned (“+”) or antialigned (“−”) along arbitrary directions are

$$F_{\pm_1\pm_2}(\hat{\theta}, \hat{\varphi}) = \frac{1}{2} [\mathbb{I}_2 \pm_1 \sigma(\theta_1, \varphi_1)] \otimes \frac{1}{2} [\mathbb{I}_2 \pm_2 \sigma(\theta_2, \varphi_2)]; \quad (13)$$

where “ \pm_i ,” $i = 1, 2$ refers to the outcome on the i ’th particle, and the notation $\hat{\theta}, \hat{\varphi}$ is used to indicate all angular parameters.

To demonstrate its physical interpretation, let us consider as a concrete example a spin state measurement on two quanta as depicted in Fig. 3: $F_{-+}(\hat{\theta}, \hat{\varphi})$ stands for the proposition

Рис. 3: Simultaneous spin state measurement of the two-partite state represented in Eq. (16). Boxes indicate spin state analyzers such as Stern-Gerlach apparatus oriented along the directions θ_1, φ_1 and θ_2, φ_2 ; their two output ports are occupied with detectors associated with the outcomes “+” and “-”, respectively.

‘The spin state of the first particle measured along θ_1, φ_1 is “-” and the spin state of the second particle measured along θ_2, φ_2 is “+”.’

More generally, we will consider two different numbers λ_+ and λ_- , and the generalized single-particle operator

$$R_{\frac{1}{2}}(\theta, \varphi) = \lambda_- \left\{ \frac{1}{2} [\mathbb{I}_2 - \sigma(\theta, \varphi)] \right\} + \lambda_+ \left\{ \frac{1}{2} [\mathbb{I}_2 + \sigma(\theta, \varphi)] \right\}, \quad (14)$$

as well as the resulting two-particle operator

$$R_{\frac{1}{2}\frac{1}{2}}(\hat{\theta}, \hat{\varphi}) = R_{\frac{1}{2}}(\theta_1, \varphi_1) \otimes R_{\frac{1}{2}}(\theta_2, \varphi_2) = \lambda_- \lambda_- F_{--} + \lambda_- \lambda_+ F_{-+} + \lambda_+ \lambda_- F_{+-} + \lambda_+ \lambda_+ F_{++}. \quad (15)$$

Singlet state

In what follows, singlet states $|\Psi_{d,n,i}\rangle$ will be labeled by three numbers d, n and i , denoting the number d of outcomes associated with the dimension of Hilbert space per particle, the number n of participating particles, and the state count i in an enumeration of all possible singlet states of n particles of spin $j = (d-1)/2$, respectively. For $n=2$, there is only one singlet state, and $i=1$ is always one.

Consider the *singlet* “Bell” state of two spin- $\frac{1}{2}$ particles

$$|\Psi_{2,2,1}\rangle = \frac{1}{\sqrt{2}}(|+-\rangle - |-+\rangle). \quad (16)$$

With the identifications $|+\rangle \equiv \hat{\mathbf{e}}_1 = (1, 0)$ and $|-\rangle \equiv \hat{\mathbf{e}}_2 = (0, 1)$ as before, the Bell state has a vector representation as

$$|\Psi_{2,2,1}\rangle \equiv \frac{1}{\sqrt{2}} (\hat{\mathbf{e}}_1 \otimes \hat{\mathbf{e}}_2 - \hat{\mathbf{e}}_2 \otimes \hat{\mathbf{e}}_1) = \frac{1}{\sqrt{2}} [(1, 0) \otimes (0, 1) - (0, 1) \otimes (1, 0)] = \left(0, \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, 0\right). \quad (17)$$

The density operator $\rho_{\Psi_{2,2,1}}$ is just the projector of the dyadic product of this vector, corresponding to the one-dimensional linear subspace spanned by $|\Psi_{2,2,1}\rangle$; i.e.,

$$\rho_{\Psi_{2,2,1}} = |\Psi_{2,2,1}\rangle \langle \Psi_{2,2,1}| = [|\Psi_{2,2,1}\rangle, |\Psi_{2,2,1}\rangle^\dagger] = \frac{1}{2} \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \quad (18)$$

Singlet states are form invariant with respect to arbitrary unitary transformations in the single-particle Hilbert spaces and thus also rotationally invariant in configuration space, in particular under the rotations $|+\rangle = e^{i\frac{\varphi}{2}} (\cos \frac{\theta}{2} |+\rangle' - \sin \frac{\theta}{2} |-\rangle')$ and $|-\rangle = e^{-i\frac{\varphi}{2}} (\sin \frac{\theta}{2} |+\rangle' + \cos \frac{\theta}{2} |-\rangle')$ in the spherical coordinates θ, φ defined above [e.g., Ref. [39], Eq. (2), or Ref. [40], Eq. (7–49)].

The Bell singlet state is unique in the sense that the outcome of a spin state measurement along a particular direction on one particle “fixes” also the opposite outcome of a spin state measurement along *the same* direction on its “partner” particle: (assuming lossless devices) whenever a “plus” or a “minus” is recorded on one side, a “minus” or a “plus” is recorded on the other side, and *vice versa*.

Results

We now turn to the calculation of quantum predictions. The joint probability to register the spins of the two particles in state $\rho_{\Psi_{2,2,1}}$ aligned or antialigned along the directions defined by (θ_1, φ_1) and (θ_2, φ_2) can be evaluated by a straightforward calculation of

$$P_{\Psi_{2,2,1} \pm_1 \pm_2}(\hat{\theta}, \hat{\varphi}) = \text{Tr} \left[\rho_{\Psi_{2,2,1}} \cdot F_{\pm_1 \pm_2}(\hat{\theta}, \hat{\varphi}) \right] = \frac{1}{4} \{ 1 - (\pm_1 1)(\pm_2 1) [\cos \theta_1 \cos \theta_2 + \sin \theta_1 \sin \theta_2 \cos(\varphi_1 - \varphi_2)] \}. \quad (19)$$

Again, “ \pm_i ,” $i = 1, 2$ refers to the outcome on the i 'th particle.

Since $P_+ + P_- = 1$ and $E = P_+ - P_-$, the joint probabilities to find the two particles in an even or in an odd number of spin-“ $-\frac{1}{2}$ ”-states when measured along (θ_1, φ_1) and (θ_2, φ_2) are in terms of the correlation coefficient given by

$$\begin{aligned} P_+ &= P_{++} + P_{--} = \frac{1}{2} (1 + E) = \frac{1}{2} \{ 1 - [\cos \theta_1 \cos \theta_2 - \sin \theta_1 \sin \theta_2 \cos(\varphi_1 - \varphi_2)] \}, \\ P_- &= P_{+-} + P_{-+} = \frac{1}{2} (1 - E) = \frac{1}{2} \{ 1 + [\cos \theta_1 \cos \theta_2 + \sin \theta_1 \sin \theta_2 \cos(\varphi_1 - \varphi_2)] \}. \end{aligned} \quad (20)$$

Finally, the quantum mechanical correlation coefficient is obtained by the difference $P_+ - P_-$; i.e.,

$$E_{\Psi_{2,2,1} -1, +1}(\theta_1, \theta_2, \varphi_1, \varphi_2) = -[\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2]. \quad (21)$$

By setting either the azimuthal angle differences equal to zero, or by assuming measurements in the plane perpendicular to the direction of particle propagation, i.e., with $\theta_1 = \theta_2 = \frac{\pi}{2}$, one obtains

$$\begin{aligned} E_{\Psi_{2,2,1} -1, +1}(\theta_1, \theta_2) &= -\cos(\theta_1 - \theta_2), \\ E_{\Psi_{2,2,1} -1, +1}(\frac{\pi}{2}, \frac{\pi}{2}, \varphi_1, \varphi_2) &= -\cos(\varphi_1 - \varphi_2). \end{aligned} \quad (22)$$

The general computation of the quantum correlation coefficient for operator (15) yields

$$\begin{aligned} E_{\Psi_{2,2,1} \lambda_1 \lambda_2}(\hat{\theta}, \hat{\varphi}) &= \text{Tr} \left[\rho_{\Psi_{2,2,1}} \cdot R_{\frac{1}{2} \frac{1}{2}}(\hat{\theta}, \hat{\varphi}) \right] = \\ &= \frac{1}{4} \{ (\lambda_- + \lambda_+)^2 - (\lambda_- - \lambda_+)^2 [\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2] \}. \end{aligned} \quad (23)$$

The standard two-particle quantum mechanical correlations (21) based on the dichotomic outcomes “ -1 ” and “ $+1$ ” are obtained by setting $\lambda_+ = -\lambda_- = 1$.

A more “natural” choice of λ_{\pm} would be in terms of the spin state observables (12) in units of \hbar ; i.e., $\lambda_+ = -\lambda_- = \frac{1}{2}$. The correlation coefficient of these observables can be directly calculated *via* $S_{\frac{1}{2}}$; i.e.,

$$\begin{aligned} E_{\Psi_{2,2,1} -\frac{1}{2}, +\frac{1}{2}}(\hat{\theta}, \hat{\varphi}) &= \text{Tr} \left\{ \rho_{\Psi_{2,2,1}} \cdot \left[S_{\frac{1}{2}}(\theta_1, \varphi_1) \otimes S_{\frac{1}{2}}(\theta_2, \varphi_2) \right] \right\} \\ &= \frac{1}{4} [\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2] = \frac{1}{4} E_{\Psi_{2,2,1} -1, +1}(\hat{\theta}, \hat{\varphi}). \end{aligned} \quad (24)$$

2.2 Three-state particles

Observables

The single particle spin one angular momentum observables in units of \hbar are given by [34]

$$M_x = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad M_y = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & -i & 0 \\ i & 0 & -i \\ 0 & i & 0 \end{pmatrix}, \quad M_z = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}. \quad (25)$$

Again, the angular momentum operator in arbitrary direction θ, φ is given by its spectral decomposition

$$\begin{aligned} S_1(\theta, \varphi) &= xM_x + yM_y + zM_z = M_x \sin \theta \cos \varphi + M_y \sin \theta \sin \varphi + M_z \cos \theta \\ &= \begin{pmatrix} \cos \theta & \frac{e^{-i\varphi} \sin \theta}{\sqrt{2}} & 0 \\ \frac{e^{i\varphi} \sin \theta}{\sqrt{2}} & 0 & \frac{e^{-i\varphi} \sin \theta}{\sqrt{2}} \\ 0 & \frac{e^{i\varphi} \sin \theta}{\sqrt{2}} & -\cos \theta \end{pmatrix} = -F_-(\theta, \varphi) + 0 \cdot F_0(\theta, \varphi) + F_+(\theta, \varphi), \end{aligned} \quad (26)$$

where the orthogonal projectors associated with the eigenstates of $S_1(\theta, \varphi)$ are

$$\begin{aligned} F_-(\theta, \varphi) &= \begin{pmatrix} \frac{\sin^4 \frac{\theta}{2}}{\sqrt{2}} & -\frac{e^{-i\varphi} \sin^2 \frac{\theta}{2} \sin \theta}{\sqrt{2}} & \frac{1}{4} e^{-2i\varphi} \sin^2 \theta \\ -\frac{e^{i\varphi} \sin^2 \frac{\theta}{2} \sin \theta}{\sqrt{2}} & \frac{\sin^2 \theta}{2} & -\frac{e^{-i\varphi} \cos^2 \frac{\theta}{2} \sin \theta}{\sqrt{2}} \\ \frac{1}{4} e^{2i\varphi} \sin^2 \theta & -\frac{e^{i\varphi} \cos^2 \frac{\theta}{2} \sin \theta}{\sqrt{2}} & \cos^4 \frac{\theta}{2} \end{pmatrix}, \\ F_0(\theta, \varphi) &= \begin{pmatrix} \frac{\sin^2 \theta}{2} & -\frac{e^{-i\varphi} \cos \theta \sin \theta}{\sqrt{2}} & -\frac{1}{2} e^{-2i\varphi} \sin^2 \theta \\ -\frac{e^{i\varphi} \cos \theta \sin \theta}{\sqrt{2}} & \cos^2 \theta & \frac{e^{-i\varphi} \cos \theta \sin \theta}{\sqrt{2}} \\ -\frac{1}{2} e^{2i\varphi} \sin^2 \theta & \frac{e^{i\varphi} \cos \theta \sin \theta}{\sqrt{2}} & \frac{\sin^2 \theta}{2} \end{pmatrix}, \\ F_+(\theta, \varphi) &= \begin{pmatrix} \cos^4 \frac{\theta}{2} & \frac{e^{-i\varphi} \cos^2 \frac{\theta}{2} \sin \theta}{\sqrt{2}} & \frac{1}{4} e^{-2i\varphi} \sin^2 \theta \\ \frac{e^{i\varphi} \cos^2 \frac{\theta}{2} \sin \theta}{\sqrt{2}} & \frac{\sin^2 \theta}{2} & \frac{e^{-i\varphi} \sin^2 \frac{\theta}{2} \sin \theta}{\sqrt{2}} \\ \frac{1}{4} e^{2i\varphi} \sin^2 \theta & \frac{e^{i\varphi} \sin^2 \frac{\theta}{2} \sin \theta}{\sqrt{2}} & \sin^4 \frac{\theta}{2} \end{pmatrix}. \end{aligned} \quad (27)$$

The orthonormal eigenstates associated with the eigenvalues $+1, 0, -1$ of $S_1(\theta, \varphi)$ in Eq. (26) are

$$\begin{aligned} |+\rangle_{\theta, \varphi} \equiv \mathbf{x}_{+1} &= e^{i\delta_{+1}} \begin{pmatrix} e^{-i\varphi} \cos^2 \frac{\theta}{2}, \frac{1}{\sqrt{2}} \sin \theta, e^{i\varphi} \sin^2 \frac{\theta}{2} \end{pmatrix}, \\ |0\rangle_{\theta, \varphi} \equiv \mathbf{x}_0 &= e^{i\delta_0} \begin{pmatrix} -\frac{1}{\sqrt{2}} e^{-i\varphi} \sin \theta, \cos \theta, \frac{1}{\sqrt{2}} e^{i\varphi} \sin \theta \end{pmatrix}, \\ |-\rangle_{\theta, \varphi} \equiv \mathbf{x}_{-1} &= e^{i\delta_{-1}} \begin{pmatrix} e^{-i\varphi} \sin^2 \frac{\theta}{2}, -\frac{1}{\sqrt{2}} \sin \theta, e^{i\varphi} \cos^2 \frac{\theta}{2} \end{pmatrix}, \end{aligned} \quad (28)$$

respectively. For vanishing angles $\theta = \varphi = 0$, $|+\rangle = (1, 0, 0)$, $|0\rangle = (0, 1, 0)$, and $|-\rangle = (0, 0, 1)$.

The generalized one-particle observable with the previous outcomes of spin state measurements “coded” into the map

$$-1 \mapsto \lambda_-, \quad 0 \mapsto \lambda_0, \quad +1 \mapsto \lambda_+ \quad (29)$$

can be written as

$$R_1(\theta, \varphi) = \lambda_- F_-(\theta, \varphi) + \lambda_0 F_0(\theta, \varphi) + \lambda_+ F_+(\theta, \varphi). \quad (30)$$

We now turn to the construction of two-partite operators.

(i) Two-partite angular momentum observable

If one is only interested in spin state measurements with the associated outcomes of spin states in units of \hbar , Eq. (26) can be used to build up the corresponding two-partite operators; i.e.,

$$S_{11}(\hat{\theta}, \hat{\varphi}) = S_1(\theta_1, \varphi_1) \otimes S_1(\theta_2, \varphi_2). \quad (31)$$

(ii) General two-partite correlation observables

The two-particle joint operator corresponding to $R_1(\theta, \varphi)$ is

$$R_{11}(\hat{\theta}, \hat{\varphi}) = R_1(\theta_1, \varphi_1) \otimes R_1(\theta_2, \varphi_2). \quad (32)$$

For the sake of the physical interpretation of this generalized operator (32), let us consider as a concrete example a spin state measurement on two quanta as depicted in Fig. 4: $\lambda_- F_-(\theta_1, \varphi_1) \otimes \lambda_+ F_+(\theta_2, \varphi_2)$ stands for the proposition

‘The outcome of the first particle measured along θ_1, φ_1 is “ λ_- ” and the outcome of the second particle measured along θ_2, φ_2 is “ λ_+ ”.’

(iii) Two-partite Kochen-Specker observables

For the sake of an operationalization of the 117 contexts contained in their proof, Kochen and Specker [15] introduced an observable based on spin one with degenerate eigenvalues corresponding to $\lambda_+ = \lambda_- = 1$ and $\lambda_0 = 0$, or its “inverted” form $\lambda_+ = \lambda_- = 0$ and $\lambda_0 = 1$. The corresponding correlation functions will be discussed below.

Рис. 4: Simultaneous measurement of the two particles with three outcome per particle. Boxes indicate spin state analyzers such as Stern-Gerlach apparatus oriented along the directions θ_1, φ_1 and θ_2, φ_2 ; their two output ports are occupied with detectors associated with the outcomes “ λ_+ ,” “ λ_0 ” and “ λ_- ”, respectively.

Singlet state

Consider the two spin-one particle singlet state

$$|\Psi_{3,2,1}\rangle = \frac{1}{\sqrt{3}} (-|00\rangle + |-+\rangle + |+ -\rangle). \quad (33)$$

Its vector space representation can be explicitly enumerated by taking the direction $\theta = \varphi = 0$ and recalling that $|+\rangle \equiv (1, 0, 0)$, $|0\rangle \equiv (0, 1, 0)$, and $|-\rangle \equiv (0, 0, 1)$; i.e.,

$$|\Psi_{3,2,1}\rangle \equiv \frac{1}{\sqrt{3}} (0, 0, 1, 0, -1, 0, 1, 0, 0). \quad (34)$$

Results

- (i) Expectation of general two-partite observables

The general computation of the quantum correlation coefficient for operator (32) yields

$$\begin{aligned} E_{\Psi_{3,2,1} \lambda_- \lambda_0 \lambda_+}(\hat{\theta}, \hat{\varphi}) &= \text{Tr} \left[\rho_{\Psi_{3,2,1}} \cdot R_{11}(\hat{\theta}, \hat{\varphi}) \right] = \\ &= \frac{1}{192} \left\{ 24\lambda_0^2 + 40\lambda_0(\lambda_- + \lambda_+) + 22(\lambda_- + \lambda_+)^2 - 32(\lambda_- - \lambda_+)^2 \cos \theta_1 \cos \theta_2 + \right. \\ &\quad + 2(-2\lambda_0 + \lambda_- + \lambda_+)^2 \cos(2\theta_2) \left[(3 + \cos(2(\varphi_1 - \varphi_2))) \cos(2\theta_1) + 2\sin(\varphi_1 - \varphi_2)^2 \right] + \\ &\quad + 2(-2\lambda_0 + \lambda_- + \lambda_+)^2 \left[\cos(2(\varphi_1 - \varphi_2)) + 2\cos(2\theta_1) \sin(\varphi_1 - \varphi_2)^2 \right] - \\ &\quad - 32(\lambda_- - \lambda_+)^2 \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2 + \\ &\quad \left. + 8(-2\lambda_0 + \lambda_- + \lambda_+)^2 \cos(\varphi_1 - \varphi_2) \sin(2\theta_1) \sin(2\theta_2) \right\}. \end{aligned} \quad (35)$$

- (ii) Expectation of two-partite angular momentum observable

For the sake of comparison, let us relate the rather lengthy correlation coefficient in Eq. (35) to the standard quantum mechanical correlations (21) and (22) based on the dichotomic outcomes by either using S_{11} from Eq. (31), or by setting $\lambda_0 = 0$, $\lambda_+ = +1$ and $\lambda_- = -1$. With these identifications,

$$E_{\Psi_{3,2,1} -1, 0, +1}(\hat{\theta}, \hat{\varphi}) = -\frac{2}{3} [\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2] = \frac{2}{3} E_{\Psi_{2,2,1} -1, +1}(\hat{\theta}, \hat{\varphi}). \quad (36)$$

This correlation coefficient is functionally identical with the spin one-half (two outcomes) correlation coefficients.

(iii) Expectation of two-partite Kochen-Specker observables

The correlation coefficient resulting from the Kochen-Specker observable corresponding to $\lambda_+ = \lambda_- = 1$ and $\lambda_0 = 0$ or its inverted form $\lambda_+ = \lambda_- = 0$ and $\lambda_0 = 1$ is

$$\begin{aligned}
 E_{\Psi_{3,2,1}+1,0,+1}(\hat{\theta}, \hat{\varphi}) &= \frac{1}{24} \{11 + \cos[2(\varphi_1 - \varphi_2)] + 4 \cos(\varphi_1 - \varphi_2) \sin(2\theta_1) \sin(2\theta_2) + \\
 &\quad + 2 [\cos(2\theta_1) + \cos(2\theta_2)] \sin^2(\varphi_1 - \varphi_2) + \\
 &\quad + \cos(2\theta_1) \cos(2\theta_2) [\cos(2(\varphi_1 - \varphi_2)) + 3]\}, \\
 E_{\Psi_{3,2,1}0,+1,0}(\hat{\theta}, \hat{\varphi}) &= \frac{1}{3} [\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2]^2, \\
 E_{\Psi_{3,2,1}+1,0,+1}(\frac{\pi}{2}, \frac{\pi}{2}, \hat{\varphi}) &= \frac{1}{6} \{\cos[2(\varphi_1 - \varphi_2)] + 3\}, \\
 E_{\Psi_{3,2,1}0,+1,0}(\frac{\pi}{2}, \frac{\pi}{2}, \hat{\varphi}) &= \frac{1}{3} \cos^2(\varphi_1 - \varphi_2), \\
 E_{\Psi_{3,2,1}+1,0,+1}(\hat{\theta}, 0, 0) &= \frac{1}{6} \{\cos[2(\theta_1 - \theta_2)] + 3\}, \\
 E_{\Psi_{3,2,1}0,+1,0}(\hat{\theta}, 0, 0) &= \frac{1}{3} \cos^2(\theta_1 - \theta_2).
 \end{aligned} \tag{37}$$

By comparing the quantum correlation coefficient $E_{\Psi_{3,2,1}-1,0,+1}(\hat{\theta}, 0, 0) \propto -\cos(\theta_1 - \theta_2)$ of the spin operators in Eq. (36) with the quantum correlation coefficient of the Kochen Specker operators $E_{\Psi_{3,2,1}+1,0,+1}(\hat{\theta}, 0, 0) \propto \cos[2(\theta_1 - \theta_2)]$ of Eq. (37), one could, for higher-than one-half angular momentum observables, envision an “enhancement” of the quantum correlation coefficient by adding weighted correlation coefficients, generated from different labels λ_i . Indeed, in the domain $0 < |\theta_1 - \theta_2| < \frac{\pi}{3}$, the plasticity of $E_{\Psi_{l,2,1} \lambda_{-1}, \lambda_0, \lambda_{+1}}$ can be used to build up “enhanced” quantum correlations *via*

$$\begin{aligned}
 &\frac{1}{2} \left\{ E_{\Psi_{3,2,1}-1,0,+1}(\hat{\theta}, 0, 0) + 3 \left[2E_{\Psi_{3,2,1}+1,0,+1}(\hat{\theta}, 0, 0) - 1 \right] \right\} \\
 &= \frac{1}{2} [-\cos(\theta_1 - \theta_2) + \cos 2(\theta_1 - \theta_2)] \\
 &< -\cos(\theta_1 - \theta_2) = E_{\Psi_{2,2,1}-1,+1}(\hat{\theta}, 0, 0)
 \end{aligned} \tag{38}$$

2.3 Four-state particles

Observables

The spin three-half angular momentum observables in units of \hbar are given by [34]

$$M_x = \frac{1}{2} \begin{pmatrix} 0 & \sqrt{3} & 0 & 0 \\ \sqrt{3} & 0 & 2 & 0 \\ 0 & 2 & 0 & \sqrt{3} \\ 0 & 0 & \sqrt{3} & 0 \end{pmatrix}, \quad M_y = \frac{1}{2} \begin{pmatrix} 0 & -\sqrt{3}i & 0 & 0 \\ \sqrt{3}i & 0 & -2i & 0 \\ 0 & 2i & 0 & -\sqrt{3}i \\ 0 & 0 & \sqrt{3}i & 0 \end{pmatrix}, \quad M_z = \frac{1}{2} \begin{pmatrix} 3 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -3 \end{pmatrix}. \tag{39}$$

Again, the angular momentum operator in arbitrary direction θ, φ can be written in its spectral form

$$\begin{aligned}
 S_{\frac{3}{2}}(\theta, \varphi) &= xM_x + yM_y + zM_z = M_x \sin \theta \cos \varphi + M_y \sin \theta \sin \varphi + M_z \cos \theta \\
 &= \begin{pmatrix} \frac{3 \cos \theta}{2} & \frac{\sqrt{3}}{2} e^{-i\varphi} \sin \theta & 0 & 0 \\ \frac{\sqrt{3}}{2} e^{i\varphi} \sin \theta & \frac{\cos \theta}{2} & e^{-i\varphi} \sin \theta & 0 \\ 0 & e^{i\varphi} \sin \theta & -\frac{\cos \theta}{2} & \frac{\sqrt{3}}{2} e^{-i\varphi} \sin \theta \\ 0 & 0 & \frac{\sqrt{3}}{2} e^{i\varphi} \sin \theta & -\frac{3 \cos \theta}{2} \end{pmatrix} \\
 &= -\frac{3}{2} F_{-\frac{3}{2}}(\theta, \varphi) - \frac{1}{2} F_{-\frac{1}{2}}(\theta, \varphi) + \frac{1}{2} F_{+\frac{1}{2}}(\theta, \varphi) + \frac{3}{2} F_{+\frac{3}{2}}(\theta, \varphi).
 \end{aligned} \tag{40}$$

If one is only interested in spin state measurements with the associated outcomes of spin states in units of \hbar , the associated two-particle operator is given by

$$S_{11}(\hat{\theta}, \hat{\varphi}) = S_1(\theta_1, \varphi_1) \otimes S_1(\theta_2, \varphi_2). \tag{41}$$

More generally, one could define a two-particle operator by

$$F_{\lambda_{-\frac{3}{2}}, \lambda_{-\frac{1}{2}}, \lambda_{+\frac{1}{2}}, \lambda_{+\frac{3}{2}}}^2(\hat{\theta}, \hat{\varphi}) = F_{\lambda_{-\frac{3}{2}}, \lambda_{-\frac{1}{2}}, \lambda_{+\frac{1}{2}}, \lambda_{+\frac{3}{2}}}(\theta_1, \varphi_1) \otimes F_{\lambda_{-\frac{3}{2}}, \lambda_{-\frac{1}{2}}, \lambda_{+\frac{1}{2}}, \lambda_{+\frac{3}{2}}}(\theta_2, \varphi_2), \tag{42}$$

Рис. 5: Simultaneous measurement of the two particles with four outcome per particle. Boxes indicate spin state analyzers such as Stern-Gerlach apparatus oriented along the directions θ_1, φ_1 and θ_2, φ_2 ; their two output ports are occupied with detectors associated with the outcomes “ $\lambda_{+\frac{3}{2}}$,” “ $\lambda_{+\frac{1}{2}}$,” “ $\lambda_{-\frac{1}{2}}$ ” and “ $\lambda_{-\frac{3}{2}}$,” respectively.

where

$$F_{\lambda_{-\frac{3}{2}}, \lambda_{-\frac{1}{2}}, \lambda_{+\frac{1}{2}}, \lambda_{+\frac{3}{2}}}(\theta, \varphi) = \lambda_{-\frac{3}{2}} F_{-\frac{3}{2}}(\theta, \varphi) + \lambda_{-\frac{1}{2}} F_{-\frac{1}{2}}(\theta, \varphi) + \lambda_{+\frac{1}{2}} F_{+\frac{1}{2}}(\theta, \varphi) + \lambda_{+\frac{3}{2}} F_{+\frac{3}{2}}(\theta, \varphi). \quad (43)$$

For the sake of the physical interpretation of this operator (42), let us consider as a concrete example a spin state measurement on two quanta as depicted in Fig. 5: $F_{\lambda_{-\frac{3}{2}}}(\theta_1, \varphi_1) \otimes F_{\lambda_{+\frac{3}{2}}}(\theta_2, \varphi_2)$ stands for the proposition

‘The outcome of the first particle measured along θ_1, φ_1 is “ $\lambda_{-\frac{3}{2}}$ ” and the outcome of the second particle measured along θ_2, φ_2 is “ $\lambda_{+\frac{3}{2}}$ ” .’

Singlet state

The singlet state of two spin-3/2 observables can be found by the general methods developed in Ref. [41]. In this case, this amounts to summing all possible two-partite states yielding zero angular momentum, multiplied with the corresponding Clebsch-Gordan coefficients

$$\langle j_1 m_1 j_2 m_2 | 00 \rangle = \delta_{j_1, j_2} \delta_{m_1, -m_2} \frac{(-1)^{j_1 - m_1}}{\sqrt{2j_1 + 1}} \quad (44)$$

of mutually negative single particle states resulting in total angular momentum zero. More explicitly, for $j_1 = j_2 = \frac{3}{2}$,

$$|\psi_{4,2,1}\rangle = \frac{1}{2} \left(\left| \frac{3}{2}, -\frac{3}{2} \right\rangle - \left| -\frac{3}{2}, \frac{3}{2} \right\rangle - \left| \frac{1}{2}, -\frac{1}{2} \right\rangle + \left| -\frac{1}{2}, \frac{1}{2} \right\rangle \right). \quad (45)$$

Again, this two-partite singlet state satisfies the uniqueness property. The four different spin states can be identified with the cartesian basis of fourdimensional Hilbert space $|\frac{3}{2}\rangle \equiv (1, 0, 0, 0)$, $|\frac{1}{2}\rangle \equiv (0, 1, 0, 0)$, $|\frac{-1}{2}\rangle \equiv (0, 0, 1, 0)$, and $|\frac{-3}{2}\rangle \equiv (0, 0, 0, 1)$, respectively.

Results

For the sake of comparison, let us again specify the rather lengthy correlation coefficient in the case of general observables with arbitrary outcomes λ_i , $i = 1, \dots, 4$ to the standard quantum mechanical correlations (24) and (36) by setting $\lambda_{+\frac{3}{2}} = +\frac{3}{2}$, $\lambda_{+\frac{1}{2}} = +\frac{1}{2}$, $\lambda_{-\frac{1}{2}} = -\frac{1}{2}$ and $\lambda_{-\frac{3}{2}} = -\frac{3}{2}$; i.e., by substituting the general outcomes with spin

state observables in units of \hbar . With these identifications, the correlation coefficients can be directly calculated *via* $S_{\frac{3}{2}\frac{3}{2}}$; i.e.,

$$\begin{aligned} E_{\Psi_{4,2,1}-\frac{3}{2},-\frac{1}{2},+\frac{1}{2},+\frac{3}{2}}(\hat{\theta}, \hat{\varphi}) &= \text{Tr} \left\{ \rho_{\Psi_{4,2,1}} \cdot \left[S_{\frac{3}{2}}(\theta_1, \varphi_1) \otimes S_{\frac{3}{2}}(\theta_2, \varphi_2) \right] \right\} \\ &= -\frac{5}{4} [\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2] \\ &= \frac{8}{15} E_{\Psi_{2,3,1}-1,+1}(\hat{\theta}, \hat{\varphi}) \\ &= 5 E_{\Psi_{2,2,1}-\frac{1}{2},+\frac{1}{2}}(\hat{\theta}, \hat{\varphi}) = \frac{5}{4} E_{\Psi_{2,2,1}-1,+1}(\hat{\theta}, \hat{\varphi}) \end{aligned} \quad (46)$$

This correlation coefficient is again functionally identical with the spin one-half and spin one (two and three outcomes) correlation coefficients.

The plasticity of the general correlation coefficient

$$E_{\Psi_{4,2,1} \lambda_{-\frac{3}{2}}, \lambda_{-\frac{1}{2}}, \lambda_{+\frac{1}{2}}, \lambda_{+\frac{3}{2}}}(\hat{\theta}, \hat{\varphi}) = \text{Tr} \left[\rho_{\Psi_{4,2,1}} \cdot F_{\lambda_{-\frac{3}{2}}, \lambda_{-\frac{1}{2}}, \lambda_{+\frac{1}{2}}, \lambda_{+\frac{3}{2}}}^2(\hat{\theta}, \hat{\varphi}) \right] \quad (47)$$

can be demonstrated by enumerating special cases; e.g.,

$$\begin{aligned} E_{\Psi_{4,2,1}-1,-1,+1,+1}(\theta, 0, 0, 0) &= \frac{1}{8} [-7 \cos \theta - \cos(3\theta)], \\ E_{\Psi_{4,2,1}-1,+1,+1,-1}(\theta, 0, 0, 0) &= \frac{1}{4} [3 \cos(2\theta) + 1], \\ E_{\Psi_{4,2,1}+1,-1,+1,-1}(\theta, 0, 0, 0) &= \frac{1}{2} [-\cos \theta - \cos(3\theta)]. \end{aligned} \quad (48)$$

These functions are drawn in Fig. 6, together with the spin state correlation coefficient $\frac{4}{5} E_{\Psi_{4,2,1}-\frac{3}{2},-\frac{1}{2},+\frac{1}{2},+\frac{3}{2}}(\theta, 0, 0, 0) = -\cos \theta$ and the classical linear correlation coefficient $E_{\text{cl},2,2}(\theta) = 2\theta/\pi - 1$ in Eq. (2).

Рис. 6: Plasticity of the correlation coefficient of two spin three-half quanta in a singlet state. (a) $E_{\Psi_{4,2,1}-1,-1,+1,+1}$ is represented by the long-dashed blue curve, (b) $E_{\Psi_{4,2,1}-1,+1,+1,-1}$ is represented by the dashed-dotted red curve, (c) $E_{\Psi_{4,2,1}+1,-1,+1,-1}$ is represented by the short-dashed green curve, (d) $\frac{4}{5} E_{\Psi_{4,2,1}-\frac{3}{2},-\frac{1}{2},+\frac{1}{2},+\frac{3}{2}}$ is represented by the dotted orange curve, and (e) $E_{\text{cl},2,2}(\theta)$ is represented by the classical linear black line.

2.4 General case of two spin j particles

We shall next treat the general case of spin correlation values of two particles with arbitrary spin j (see the Appendix of Ref. [42] for a group theoretic derivation).

Observables

In full generality, the matrix representation of the spin j angular momentum observables in units of \hbar are given by

$$\begin{aligned} (M_x)_{m,n} &= \frac{1}{2}\sqrt{j(j+1)-m(m-1)}\delta_{m,n+1} + \frac{1}{2}\sqrt{j(j+1)-m(m+1)}\delta_{m,n-1}, \\ (M_y)_{m,n} &= \frac{i}{2}\sqrt{j(j+1)-m(m-1)}\delta_{m,n+1} - \frac{i}{2}\sqrt{j(j+1)-m(m+1)}\delta_{m,n-1}, \\ (M_z)_{m,n} &= m\delta_{mn}, \end{aligned} \quad (49)$$

where $m, n = -j, -j+1, \dots, j-1, j$.

Again, the angular momentum operator in arbitrary direction θ, φ in units of \hbar can be written as

$$S_j(\theta, \varphi) = xM_x + yM_y + zM_z = M_x \sin \theta \cos \varphi + M_y \sin \theta \sin \varphi + M_z \cos \theta. \quad (50)$$

If one is interested in spin state measurements with the associated outcomes of spin states in units of \hbar , the associated two-particle operator is given by

$$S_{jj}(\hat{\theta}, \hat{\varphi}) = S_j(\theta_1, \varphi_1) \otimes S_j(\theta_2, \varphi_2). \quad (51)$$

The physical interpretation of the operator (51) is this:

‘The outcome of the first particle measured along θ_1, φ_1 is some λ_m and the outcome of the second particle measured along θ_2, φ_2 is some $\lambda_{m'}$, where $\lambda_m, \lambda_{m'} \in \{-j, -j+1, \dots, j-1, j\}$ correspond to one of the $2j+1$ outcomes of a spin state measurement along the directions θ_1, φ_1 and θ_2, φ_2 , respectively.’

Singlet state

The singlet state of two spin- j observables can again be found by the general methods developed in Ref. [41]. A singlet state composed from just two particles can only be a “zigzag” state [41] of the form

$$\begin{aligned} |\Psi_{2,2j+1,1}\rangle &= \sum_{m=-j}^j \langle j+m, j-m | 00 \rangle | +m, -m \rangle \\ &\equiv \sum_{m=1}^{2j+1} \frac{(-1)^{1+j-m}}{\sqrt{2j+1}} \mathbf{e}_m \otimes \mathbf{e}_{2(j+1)-m}, \end{aligned} \quad (52)$$

where Eq. (44) has been used, and \mathbf{e}_m is the m 'th vector of the Cartesian basis in $2j+1$ -dimensional vector space, with m 'th component 1 and 0 otherwise.

Results

With these identifications, the correlation coefficients can be directly calculated *via* S_{jj} yielding

$$\begin{aligned} E_{\Psi_{2,2j+1,1}-j,-j+1,\dots,+j-1,+j}(\hat{\theta}, \hat{\varphi}) &= \text{Tr} \{ \rho_{\Psi_{2,2j+1,1}} \cdot [S_j(\theta_1, \varphi_1) \otimes S_j(\theta_2, \varphi_2)] \} \\ &= -\frac{j(1+j)}{3} [\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2]. \end{aligned} \quad (53)$$

Thus, the functional form of the two-particle correlation coefficients based on spin state observables is *independent* of the absolute spin value.

Рис. 7: Construction of both singlet states a) $|\Psi_{2,4,1}\rangle$ of Eq. (54) and b) $|\Psi_{2,4,2}\rangle$ of Eq. (55) of four spin- $\frac{1}{2}$ particles. Concentric circles indicate the target states. The second state is a “zigzag” state composed by the product of two two-partite singlet states. The two-dimensional diagram represents the “space” or “domain” of all multi-partite states, whereby the *number of particles* is represented by the abscissa (the x -coordinate) along the positive x -axis. The ordinate (the y -coordinate) of the state is equal the total angular momentum of the state. Note that a single point may represent many states; all corresponding to an equal number of particles, and all having the same total angular momentum. N -partite singlet states can be constructed by starting from the unique state of one particle, then proceeding *via* all “diagonal” and, whenever possible for integer spins, also “horizontal” pathways consisting of single substeps adding one particle after the other — either diagonally from the lower left to the upper right “↗,” or diagonally from the upper left to the lower right “↘,” or, if possible, also horizontally from left to right “→” — towards the zero momentum state of N particles. Every diagonal or horizontal substep corresponds to the addition of a single particle.

3. Four spin one-half particle correlations

To begin with the analysis of four-partite correlations, consider four spin- $\frac{1}{2}$ particles in one of the two singlet states generated by the two “paths” in the multipartite state space depicted in Fig. 7 (See also Ref. [41])

$$|\Psi_{2,4,1}\rangle = \frac{1}{\sqrt{3}} \left[|++--\rangle + |--++\rangle - \frac{1}{2}(|+-\rangle + |-+\rangle)(|+-\rangle + |-+\rangle) \right], \quad (54)$$

$$|\Psi_{2,4,2}\rangle = (|\Psi_{2,2,1}\rangle)^2 = \frac{1}{2}(|+-\rangle - |-+\rangle)(|+-\rangle - |-+\rangle), \quad (55)$$

where $|\Psi_{2,2,1}\rangle = \frac{1}{\sqrt{2}}(|+-\rangle - |-+\rangle)$ is the two particle singlet “Bell” state. In what follows, we shall concentrate on the first state $|\Psi_{2,4,1}\rangle$, since $|\Psi_{2,4,2}\rangle$ is just the product of two two-partite singlet states, thus presenting entanglement merely among two pairs of two quanta.

With the identification of $|+\rangle \equiv \hat{\mathbf{e}}_1 = (1, 0)$ and $|-\rangle \equiv \hat{\mathbf{e}}_2 = (0, 1)$ as before, the first singlet state has a vector representation

$$\begin{aligned} \hat{\Psi}_{2,4,1} &= \frac{1}{\sqrt{3}} \left[\hat{\mathbf{e}}_1 \otimes \hat{\mathbf{e}}_1 \otimes \hat{\mathbf{e}}_2 \otimes \hat{\mathbf{e}}_2 + \hat{\mathbf{e}}_2 \otimes \hat{\mathbf{e}}_2 \otimes \hat{\mathbf{e}}_1 \otimes \hat{\mathbf{e}}_1 \right. \\ &\quad \left. - \frac{1}{\sqrt{2}}(\hat{\mathbf{e}}_1 \otimes \hat{\mathbf{e}}_2 + \hat{\mathbf{e}}_2 \otimes \hat{\mathbf{e}}_1) \otimes \frac{1}{\sqrt{2}}(\hat{\mathbf{e}}_1 \otimes \hat{\mathbf{e}}_2 + \hat{\mathbf{e}}_2 \otimes \hat{\mathbf{e}}_1) \right] \\ &= \left(0, 0, 0, \frac{1}{\sqrt{3}}, 0, -\frac{1}{2\sqrt{3}}, -\frac{1}{2\sqrt{3}}, 0, 0, -\frac{1}{2\sqrt{3}}, -\frac{1}{2\sqrt{3}}, 0, \frac{1}{\sqrt{3}}, 0, 0, 0 \right). \end{aligned} \quad (56)$$

The density operators $\rho_{\Psi_{2,4,1}}$ is just the projector corresponding to the one-dimensional linear subspaces spanned by the vectors representing $\hat{\Psi}_{2,4,1}$ in Eq. (56); i.e., it is the dyadic product

$$\rho_{\Psi_{2,4,1}} = |\Psi_{2,4,1}\rangle\langle\Psi_{2,4,1}| = [|\Psi_{2,4,1}\rangle, |\Psi_{2,4,1}\rangle^\dagger]. \quad (57)$$

3.1 Observables

In what follows, the operators corresponding to the spin state observables will be enumerated.

The projection operators F corresponding to a four spin one-half particle joint measurement aligned (“+”) or antialigned (“−”) along those angles are

$$F_{\pm\pm\pm\pm}(\hat{\theta}, \hat{\varphi}) = \frac{1}{2} [\mathbb{I}_2 \pm \sigma(\theta_1, \varphi_1)] \otimes \frac{1}{2} [\mathbb{I}_2 \pm \sigma(\theta_2, \varphi_2)] \otimes \frac{1}{2} [\mathbb{I}_2 \pm \sigma(\theta_3, \varphi_3)] \otimes \frac{1}{2} [\mathbb{I}_2 \pm \sigma(\theta_4, \varphi_4)]. \quad (58)$$

To demonstrate its physical interpretation, let us consider a concrete example: $F_{-+--}(\hat{\theta}, \hat{\varphi})$ stands for the proposition

‘The spin state of the first particle measured along θ_1, φ_1 is “−”, the spin state of the second particle measured along θ_2, φ_2 is “+”, the spin state of the third particle measured along θ_3, φ_3 is “−”, and the spin state of the fourth particle measured along θ_4, φ_4 is “+” .’

Fig. 8 depicts a measurement configuration for a simultaneous measurement of spins along $\theta_1, \varphi_1, \theta_2, \varphi_2, \theta_3, \varphi_3$ and θ_4, φ_4 of the state $\Psi_{2,4,1}$.

3.2 Probabilities and correlations

The joint probability to register the spins of the four particles in state $\Psi_{2,4,1}$ aligned or antialigned along the directions defined by (θ_1, φ_1) , (θ_2, φ_2) , (θ_3, φ_3) , and (θ_4, φ_4) can be evaluated by a straightforward calculation of

$$P_{\Psi_{2,4,1}\pm 1, \pm 1, \pm 1, \pm 1}(\hat{\theta}, \hat{\varphi}) = \text{Tr} \left[\rho_{\Psi_{2,4,1}} \cdot F_{\pm\pm\pm\pm}(\hat{\theta}, \hat{\varphi}) \right]. \quad (59)$$

Рис. 8: Simultaneous spin measurement of the four-partite singlet state represented in Eq. (55). Boxes indicate spin state analyzers such as Stern-Gerlach apparatus oriented along the directions $\theta_1, \varphi_1, \theta_2, \varphi_2, \theta_3, \varphi_3$ and θ_4, φ_4 ; their two output ports are occupied with detectors associated with the outcomes “+” and “-”, respectively.

The correlation coefficients and joint probabilities to find the four particles in an even or in an odd number of spin-“-”-states when measured along $(\theta_1, \varphi_1), (\theta_2, \varphi_2), (\theta_3, \varphi_3)$, and (θ_4, φ_4) obey $P_{\text{even}} + P_{\text{odd}} = 1$, as well as $E = P_{\text{even}} - P_{\text{odd}}$; hence $P_{\text{even}} = \frac{1}{2} [1 + E]$ and $P_{\text{odd}} = \frac{1}{2} [1 - E]$. Thus, the four particle quantum correlation is given by (cf. Table 1)

$$E_{\Psi_{2,4,1-1,+1}}(\hat{\theta}, \hat{\varphi}) = \frac{1}{3} \{ \cos \theta_3 \sin \theta_1 [-\cos \theta_4 \cos(\varphi_1 - \varphi_2) \sin \theta_2 + 2 \cos \theta_2 \cos(\varphi_1 - \varphi_4) \sin \theta_4] + \\ \sin \theta_1 \sin \theta_3 [2 \cos \theta_2 \cos \theta_4 \cos(\varphi_1 - \varphi_3) + \\ (2 \cos(\varphi_1 + \varphi_2 - \varphi_3 - \varphi_4) + \cos(\varphi_1 - \varphi_2) \cos(\varphi_3 - \varphi_4)) \sin \theta_2 \sin \theta_4] + \\ \cos \theta_1 [2 \sin \theta_2 (\cos \theta_4 \cos(\varphi_2 - \varphi_3) \sin \theta_3 + \cos \theta_3 \cos(\varphi_2 - \varphi_4) \sin \theta_4) + \\ \cos \theta_2 (3 \cos \theta_3 \cos \theta_4 - \cos(\varphi_3 - \varphi_4) \sin \theta_3 \sin \theta_4)] \}. \quad (60)$$

If all the polar angles $\hat{\theta}$ are set to $\pi/2$, then this correlation function yields

$$E_{\Psi_{2,4,1-1,+1}}(\frac{\pi}{2}, \frac{\pi}{2}, \frac{\pi}{2}, \frac{\pi}{2}, \hat{\varphi}) = \frac{1}{3} [2 \cos(\varphi_1 + \varphi_2 - \varphi_3 - \varphi_4) + \cos(\varphi_1 - \varphi_2) \cos(\varphi_3 - \varphi_4)]. \quad (61)$$

Likewise, if all the azimuthal angles $\hat{\varphi}$ are all set to zero, one obtains

$$E_{\Psi_{2,4,1-1,+1}}(\hat{\theta}) = \frac{1}{3} [2 \cos(\theta_1 + \theta_2 - \theta_3 - \theta_4) + \cos(\theta_1 - \theta_2) \cos(\theta_3 - \theta_4)]. \quad (62)$$

The plasticity of the correlation coefficient $E_{\Psi_{2,4,1-1,+1}}(\hat{\theta})$ of Eq. (62) for various parameter values θ is depicted in Fig. 9.

4. Summary

Compared to the two-partite quantum correlations of two-state particles, the plasticity of the quantum correlations of states of *more than two particles* originates in the dependency of the *multitude of angles* involved, as well as by the *multitude of singlet states* in this domain. For states composed from particles of *more than two mutually exclusive outcomes*, the plasticity is also increased by the *different values associated with the outcomes*.

Рис. 9: Plasticity of the correlation coefficient of four spin one-half quanta in a singlet state. (a) $E_{\Psi_{2,4,1-1,+1}}(\theta, \frac{\pi}{4}, -\theta, \theta)$ is represented by the long-dashed blue curve, (b) $E_{\Psi_{2,4,1-1,+1}}(\theta, \theta, -\theta, \theta)$ is represented by the dashed-dotted red curve, (c) $E_{\Psi_{2,4,1-1,+1}}(\theta, -\theta, -\theta, \theta)$ is represented by the short-dashed green curve, (d) $E_{\Psi_{2,4,1-1,+1}}(\theta, -\theta, -\theta, 0)$ is represented by the dotted orange curve, and (e) $E_{\Psi_{2,4,1-1,+1}}(-\theta, -\theta, \frac{\pi}{4}, \theta)$ is represented by the solid magenta line.

$P_{\text{even}} = \frac{1}{2} [1 + E] , P_{\text{odd}} = \frac{1}{2} [1 - E] , E = P_{\text{even}} - P_{\text{odd}}$	
$E_{\Psi_{2,4,1-1,+1}}(\hat{\theta}, \hat{\varphi})$	$= \frac{1}{3} \{ \cos \theta_3 \sin \theta_1 [- \cos \theta_4 \cos(\varphi_1 - \varphi_2) \sin \theta_2 + 2 \cos \theta_2 \cos(\varphi_1 - \varphi_4) \sin \theta_4] +$ $\sin \theta_1 \sin \theta_3 [2 \cos \theta_2 \cos \theta_4 \cos(\varphi_1 - \varphi_3) +$ $(2 \cos(\varphi_1 + \varphi_2 - \varphi_3 - \varphi_4) + \cos(\varphi_1 - \varphi_2) \cos(\varphi_3 - \varphi_4)) \sin \theta_2 \sin \theta_4] +$ $\cos \theta_1 [2 \sin \theta_2 (\cos \theta_4 \cos(\varphi_2 - \varphi_3) \sin \theta_3 + \cos \theta_3 \cos(\varphi_2 - \varphi_4) \sin \theta_4) +$ $\cos \theta_2 (3 \cos \theta_3 \cos \theta_4 - \cos(\varphi_3 - \varphi_4) \sin \theta_3 \sin \theta_4)] \}$
$E_{\Psi_{2,4,1-1,+1}}(\hat{\theta})$	$= \frac{1}{3} [2 \cos(\theta_1 + \theta_2 - \theta_3 - \theta_4) + \cos(\theta_1 - \theta_2) \cos(\theta_3 - \theta_4)] .$
$E_{\Psi_{2,4,1-1,+1}}(\frac{\pi}{2}, \frac{\pi}{2}, \frac{\pi}{2}, \frac{\pi}{2}, \hat{\varphi})$	$= \frac{1}{3} [2 \cos(\varphi_1 + \varphi_2 - \varphi_3 - \varphi_4) + \cos(\varphi_1 - \varphi_2) \cos(\varphi_3 - \varphi_4)]$
$E_{\Psi_{2,4,2-1,+1}}(\hat{\theta}, \hat{\varphi})$	$= \frac{[\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2] \cdot}{[\cos \theta_3 \cos \theta_4 + \cos(\varphi_3 - \varphi_4) \sin \theta_3 \sin \theta_4]}$
$E_{\Psi_{2,4,2-1,+1}}(\hat{\theta})$	$= \cos(\theta_1 - \theta_2) \cos(\theta_3 - \theta_4),$
$E_{\Psi_{2,4,2-1,+1}}(\frac{\pi}{2}, \frac{\pi}{2}, \frac{\pi}{2}, \frac{\pi}{2}, \hat{\varphi})$	$= \cos(\varphi_1 - \varphi_2) \cos(\varphi_3 - \varphi_4),$

Табл. 1: Probabilities and correlation coefficients for finding an odd or even number of spin-“—”-states for both four-partite singlet states. Omitted arguments are zero.

We have explicitly derived the quantum correlation functions of two- and four-partite spin one-half, as well as two-partite systems of higher spin. All quantum correlation coefficients of the two-partite spin observables have identical form, all being proportional to $\cos \theta_1 \cos \theta_2 + \cos(\varphi_1 - \varphi_2) \sin \theta_1 \sin \theta_2$. We have also argued that, by utilizing the plasticity of the quantum correlation coefficients for spins higher than one-half, this well-known correlation function can be “enhanced” by defining sums of quantum correlation coefficients, at least in some domains of the measurement angles.

It would be interesting to know whether this plasticity of the quantum correlations $E_{\Psi_{l,2,1} \lambda_{-l}, \dots, \lambda_{+l}}$ for “very high” angular momentum l observables could be pushed to the point of maximal violation of the Clauser-Horne-Shimony-Holt inequality *without* a bit exchange such as by using the “building up” of a step function from the individual correlation coefficients [42]; e.g., for $0 \leq \theta \leq \pi$,

$$\text{sgn}(x) = \begin{cases} -1 & \text{for } 0 \leq x < \frac{\pi}{2} \\ 0 & \text{for } x = \frac{\pi}{2} \\ +1 & \text{for } \frac{\pi}{2} < x \leq \pi \end{cases} = \frac{4}{\pi} \sum_{n=0}^{\infty} \frac{(-1)^n \cos \left[(2n+1) \left(\theta + \frac{\pi}{2} \right) \right]}{2n+1} . \quad (63)$$

Any such violation of Boole-Bell type “conditions of possible experience” beyond the maximal quantum violations, as for instance derived by Tsirelson [43] and generalized in Ref. [44] not necessarily generalizes to the multipartite, non dichotomic cases. Note also that such a strong or even maximal violation of the Boole-Bell type “conditions of possible experience” beyond the maximal quantum violations needs not necessarily violate relativistic causality [38,45], or be associated with a “sharpening” of the angular dependence of the joint occurrence of certain elementary dichotomic outcomes, such as “++,” “+−,” “−+” or “−−,” respectively.

Acknowledgments: The author gratefully acknowledges support from the Centre for Discrete Mathematics and Theoretical Computer Science (CDMTCS) of The University of Auckland, as well as discussions with Boris Kamenik, Günther Krenn and Johann Summhammer in Viennese coffee houses and elsewhere. Many ideas emerged in those conversations and also during walks through the Vienna Woods and Auckland’s Waitakere Ranges.
